Archimedes' Principle Exercise

Before you solve the problem, draw a diagram in each case.

Question 1

Case 1: A beaker is set on a scale, which reads 150 g. 1000 ml of water is poured into the beaker.

(a) What does the scale read now?

<u>Case 2</u>: A 1-kg cylindrical object suspended by a spring scale is submerged completely in the water, and the new water level is 400 ml higher than before.

- (b) What is the volume of the object?
- (c) What is the density of the object?
- (d) What does the spring scale read?
- (e) What does the scale below the beaker read?

<u>Case 3</u>: Instead of the cylinder submerged completely in water, the only half of the cylinder is submerged.

- (f) What is the new water level?
- (g) What is the density of the object?
- (h) What does the spring scale read?
- (i) What does the scale below the beaker read?

<u>Case 4</u>: Lastly, the cylinder is resting on the bottom of the scale.

- (j) What is the water level?
- (k) What does the spring scale read?
- (l) What does the scale below the beaker read?

Question 2

A beaker is set on a scale, which reads 1000 g. 1000 ml of liquid ($\rho = 2 \text{ g/cm}^3$) is poured into the beaker. When a 1-kg object is submerged completely, the scale below the beaker read 3250 g.

- (a) What does the spring scale which supports the object read now?
- (b) What is the new water level?
- (c) What is the density of the object?
